

# SSHT SURFACE TREATMENT

## SSHT Surface Treatment

The treatment is a semi-automatic process which modifies the surface molecules of the rubber, thus reducing surface tackiness and improving friction reduction and ageing characteristics of the rubber.

### The process involves:

A controlled cycle of exposure to a monovalent chemical solution, interspersed with appropriate cleaning and neutralising washes followed by a final warm air drying process.

Seals are maintained in a controlled environment throughout the cycle until final packing in clean polythene bags.

### Quality

The sequence of events, timing, temperature, media and strengths etc. are closely monitored and maintained to achieve consistently high quality.
